

**STANDARD FORMAT SPECIFICATION FOR AUTOMATICALLY
CONFIGURING IP SECURITY TUNNELS**

BACKGROUND OF THE INVENTION

5

1. Technical Field:

The present invention relates in general to a method and system for securing networks. Still more particularly, the present invention relates to an improved system and method for providing a standard format to use to configure IP security tunnels where the standard format may be used by any one of multiple, different operating systems and multiple, different machine types.

15

2. Description of Related Art:

In today's modern environment, many businesses and organizations deal with global markets and have global logistic concerns. Many organizations have facilities disbursed across the country or even around the world. Despite their global presence, these organizations need a way to maintain fast, secure and reliable communications with individuals and other offices throughout the world.

Until recently, fast, secure and reliable communication has meant the use of leased lines to maintain a Wide Area Network (WAN). Leased lines, ranging from ISDN (Integrated Services Digital Network, 144 Kbps) to OC3 (Optical Carrier-3, 155 Mbps) fiber, provided a company with a way to expand their private network beyond their immediate geographic area. A WAN had obvious advantages over a public network like the Internet when it came to reliability, performance and

Docket No. AUS920010449US1

security. But maintaining a WAN, particularly when using leased lines, can become quite expensive and often rises in cost as the distance between the offices increases. In addition, using WANs is not a scaleable solution as
5 the number of interconnections rises exponentially as new locations are added.

In essence, a Virtual Private Network, or "VPN," is a private network that uses a public network (usually the Internet) to connect remote sites or users together. To
10 make communication between computers private, VPNs use security methods, such as encryption, to maintain privacy. Instead of using a dedicated, real-world connection such as a leased line, a VPN uses "virtual" connections routed through the Internet from the
15 company's private network to the remote site or employee.

A well-designed VPN can greatly benefit a company. For example, it can: extend geographic connectivity, improve security, reduce operational costs versus traditional WAN, reduce transit time and transportation
20 costs for remote users, improve productivity, simplify network topology, provide global networking opportunities, provide telecommuter support, provide broadband networking compatibility, and provide faster ROI (Return On Investment) than traditional WAN. A
25 well-designed VPN, therefore, should incorporate features for security, reliability, scalability, network management, and policy management.

In a VPN, each remote member of the network is able to communicate in a secure and reliable manner using the
30 Internet as the medium to connect to a private local area network, or "LAN." A VPN can grow to accommodate more users and different locations much easier than a leased

Docket No. AUS920010449US1

line. In fact, scalability is a major advantage that
VPNs have over typical leased lines. Unlike leased
lines, where the cost increases in proportion to the
distances involved, the geographic locations of each
5 office matter little in the creation of a VPN.

A well-designed VPN uses several methods for keeping
connections and data secure. Firewalls provide a strong
barrier between private networks and the Internet.
Firewalls can restrict the number of open ports, what
10 type of packets are passed through, and which protocols
are allowed through. Encryption is used to encode all
the data that one computer is sending to another into a
form that only the other computer will be able to decode.
Two modes of authentication are used on VPNs: pre-shared
15 keys and digital signatures.

Pre-shared key encryption means that each partner in
a VPN has a secret "key" that it can use to authenticate
the remote identifier of a VPN. Pre-shared key
encryption requires that you know which computers will
20 talk to each other, and that you install the same key on
each one.

Digital signature authentication, on the other hand,
uses a combination of a private key and a public key.
The private key is known only to your computer while the
25 public key is given by your computer to any computer that
wants to communicate securely with it. To decode an
encrypted message, the receiving computer must use the
public key provided by the originating computer. Public
keys are bound to an identity, such as a business or a
30 user, by using "digital certificates" that are typically
issued by a trusted third party.

Docket No. AUS920010449US1

The key is based on a hash value. This is a value that is computed from a base input number using a hashing algorithm. The important thing about a hash value is that it is nearly impossible to derive the original input
5 number without knowing the data used to create the hash value. Public keys generally use complex algorithms and very large hash values for encrypting.

On a typical VPN, the authentication of the initial connection is accomplished using public key algorithm.
10 Once the connection is established and authenticated, keying material is sent from one computer to the other and the connection switches to symmetric encryption, such as DES or Triple DES. Symmetric encryption is used during data transfer because the amount of time decoding
15 data is reduced.

The Internet Protocol Security Protocol (IPsec) provides enhanced security features such as strong encryption algorithms and comprehensive authentication. IPsec has two encryption modes: tunnel and transport.
20 Tunnel mode tunnels the original packet and builds a new IP header, while transport mode inserts the IPsec payload between the IP header and the data. Systems that are IPsec compliant can take advantage of this protocol. Also, all devices negotiate security parameters, but they
25 must have compatible security policies set up. IPsec works well on both Remote-Access and Site-to-Site VPNs. IPsec must be supported at both tunnel interfaces to work.

The IPsec protocol can be used in conjunction with
30 the Internet Key Exchange security protocol (IKE). This protocol provides additional authentication and encryption features to the IPsec standard.

Docket No. AUS920010449US1

Many VPNs rely on tunneling to create a private network that reaches across the Internet. Essentially, tunneling is the process of placing an entire packet within another packet and sending it over a network. The
5 protocol of the outer packet is understood by the network and both points, called tunnel interfaces, where the packet enters and exits the VPN. Tunneling uses three different protocols: (1) carrier protocol: the protocol used by the network that the information is traveling
10 over; (2) encapsulating protocol: the protocol that is wrapped around the original data; and (3) passenger protocol: the original data (IPX, NetBeui, IP) being carried.

Tunneling has important implications for VPNs. For
15 example, a packet that uses a protocol not supported on the Internet (such as NetBeui) can be placed inside an IP packet and sent it safely over the Internet. Or a packet that uses a private (non-routable) IP address can be placed inside a packet that uses a globally unique IP
20 address in order to extend a private network over the Internet. Tunneling is also necessary for gateways because the IP header needs to have the gateway IP address in it.

An analogy of tunneling is having a computer
25 delivered to you by a courier service. The vendor packs the computer (passenger protocol) into a box (encapsulating protocol) which is then put on a courier truck (carrier protocol) at the vendor's warehouse (entry tunnel interface). The truck (carrier protocol) travels
30 over the highways (Internet) to your home (exit tunnel interface) and delivers the computer. You open the box (encapsulating protocol) and remove the computer

Docket No. AUS920010449US1

(passenger protocol).

The Internet Protocol Security Protocol (IPsec) is a set of open standards. These standards are implemented in a variety of different ways by each different
5 operating system that supports these standards. Therefore, a computer system that is initiating a communication may implement the Internet Protocol Security Protocol in one way while a computer system that is a responder computer system may implement IPsec in a
10 different way.

In known systems when a system administration needs to configure a tunnel between two computer systems that implement the IPsec protocol in different ways, the system administration must configure the tunnel manually
15 by directly inputting the various necessary parameters. This process of manually configuring the security tunnels can become very time consuming, especially in systems requiring many different tunnels.

Therefore, a need exists for a method, system, and
20 product for automatically configuring an IP security tunnel utilizing a standardized security policy specification format in computer systems using any one of different operating systems.

SUMMARY OF THE INVENTION

A data processing system, method, and product are disclosed for automatically configuring IP security tunnels. A security policy specification format is established that is capable of being utilized by any one of multiple different operating systems and any one of multiple different machine types. The format specifies a plurality of different elements that may be used to define a configuration of an IP security tunnel.

In order to define an IP security tunnel configuration, a system administrator first generates an XML file utilizing the elements defined by the standard format. This XML file defines the configuration of a particular IP security tunnel. The configuration of multiple IP security tunnels may be compared by comparing their respective XML files.

The XML file may be used by any type of machine type and any type of operating system. When the XML file is processed, it will automatically configure an IP security tunnel as defined by the elements included in the file.

The format includes elements to define the various parameters defined by the IPsec protocol and the Internet Key Exchange (IKE) protocol. The format includes elements to define separate IKE and IPsec protections. Elements are also included to describe remote and local end points, groups, and pre-shared keys.

When the format is used, tunnels can be configured to a large number of endpoints easily, quickly, and programmatically.

Docket No. AUS920010449US1

The above as well as additional objectives, features, and advantages of the present invention will become apparent in the following detailed written description.

BRIEF DESCRIPTION OF THE DRAWINGS

The novel features believed characteristic of the invention are set forth in the appended claims. The invention itself, however, as well as a preferred mode of use, further objectives and advantages thereof, will best be understood by reference to the following detailed description of an illustrative embodiment when read in conjunction with the accompanying drawings, wherein:

Figure 1 is a system diagram showing a single computer using multiple tunnels to communicate with various VPNs;

Figure 2 is a diagram showing tunnels being created between a computer and other computers using VPN configuration data and certificate data;

Figure 3 is a database diagram showing tables used in configuring tunnels between the computer and other computer systems;

Figure 4 illustrates a high level flow chart which depicts the creation of a phase 1 tunnel using VPN configuration data in accordance with the present invention;

Figure 5 depicts a high level flow chart which illustrates the details involved in creating a secure phase 1 tunnel using the VPN configuration data in accordance with the present invention;

Figure 6 illustrates a high level flow chart which depicts the steps performed in using policies to communicate through phase 1 and phase 2 processing in accordance with the present invention;

Figure 7 depicts a high level flow chart which illustrates establishing a standard format to use by any

Docket No. AUS920010449US1

operating system and any machine type to automatically
configure IP security tunnels in accordance with the
present invention; and

Figure 8 illustrates a high level flow chart which
5 depicts automatically configuring an IP security tunnel
using a standard format in accordance with the present
invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

A preferred embodiment of the present invention and its advantages are better understood by referring to the
5 figures, like numerals being used for like and corresponding parts of the accompanying figures.

The invention is preferably realized using a well-known computing platform, such as an IBM RS/6000 server running the IBM AIX operating system. However, it
10 may be realized in other popular computer system platforms, such as an IBM personal computer running the Microsoft Windows operating system or a Sun Microsystems workstation running operating systems such as UNIX or LINUX, without departing from the spirit and scope of the
15 invention.

Figure 1 shows a system diagram of a single computer using multiple tunnels to communicate with various virtual private networks (VPNs). Computer system **100** is shown using computer network **110**, such as the Internet,
20 to communicate with computers using three VPNs - VPN "A" (**120**), VPN "B" (**140**), and VPN "C" (**160**). Three tunnels are shown connecting computer system **100** to first computer system **130**, second computer system **150**, and third computer system **170**. First computer system **130** is
25 shown as a member of VPN "A" (**120**), second computer system **150** is shown as a member of VPN "B" (**140**), and third computer system **170** is shown as a member of VPN "C" (**160**). Each of the VPNs may use a different authentication means to secure the data traveling between
30 the computer systems. For example, computers within VPN "A" **120** may use a pre-shared key (i.e., a common key

Docket No. AUS920010449US1

shared amongst the computers used to derive encryption keys). VPN "B" **140**, on the other hand, may use public key encryption to encrypt the data. Finally, VPN "C" **160** may use digital signatures with digital certificates
5 verified by a trusted third party, also called a "certification authority," or "CA".

Further each of these computers may be implemented using different hardware, i.e. different machine types. Each computer system may also be utilizing a different
10 operating system.

Figure 2 shows a diagram of tunnels being created between a computer and other computers using VPN configuration data and certificate data. Computer system **200** establishes various tunnels used to securely transmit
15 data to and from other computer systems. Computer systems that computer system **200** wishes to securely communicate with over a VPN are identified in VPN configuration database **210**. VPN data **220** contains information for connecting with a particular computer
20 system. Using VPN configuration database **210**, any number of VPNs can be established between computer system **200** and other computer systems. Some VPNs use certificate data **280** supplied by a trusted third party computer system **270**. The use of a trusted third party aids in
25 authenticating users and ensuring that an impostor does not take the place of another computer system.

In the example shown, computer system **200** establishes tunnel A **235** securely connecting first computer system **230** with computer system **200**. Likewise,
30 tunnel B **245** securely connects second computer system **240** with computer system **200**, tunnel C **255** securely connects

Docket No. AUS920010449US1

third computer system **250** with computer system **200**, and tunnel D **265** securely connects fourth computer system **260** with computer system **200**. Each of these computer systems, **230**, **240**, **250**, and **260**, have identification
5 information and authentication information stored in VPN configuration database **210**.

Figure 3 shows a database diagram of tables used in configuring tunnels between the computer and other computer systems. VPN configuration database **300** is
10 shown with four tables. Endpoints table **310** includes a list of configured tunnels between the computer system and other computer systems. One end of each endpoint identifies the computer system, while the other end of the endpoint identifies a remote computer. Each of the
15 computers included in endpoints table **310** is identified with an identifier, such as an address. In addition, endpoints table **310** includes IP addresses for the remote computer systems. An IP address is an identifier for a computer or device on a TCP/IP network. Networks using
20 the TCP/IP protocol route messages based on the IP address of the destination. The format of an IP address is a 32-bit numeric address written as four numbers separated by periods. Each number can be zero to 255. For example, 1.160.10.240 could be an IP address. Within
25 an isolated network, IP addresses can be assigned at random so long as each one is unique. However, connecting a private network to the Internet requires using registered IP addresses (called Internet addresses) to avoid duplicates. The four numbers in an IP address
30 are used in different ways to identify a particular network and a host on that network. Finally, endpoints table **310** includes a flag indicating whether a

Docket No. AUS920010449US1

Certificate Revocation List (CRL) is used to check whether a given certificate has been revoked. Other valid ID types include FQDN, user@FQDN, distinguished names, and key IDs.

5 Endpoints table **310** has relationships with three other tables in VPN configuration database **300**. Each local-remote computer pair included in endpoints table **310** may have a pre-shared key stored in pre-shared keys table **330** or a public key stored in digital certificate table **340**. In some situations, a local-remote computer pair may have both a pre-shared key and a public key. Finally, a policy from policy table **320** exists for one or more set of endpoints determining the access method and preference order for connecting the local computer to a
10 given remote computer.
15

 Policy table **320** is used to employ a connection policy used by a given VPN. Typically, one policy exists for each VPN that the local machine uses. Policy table **320** includes the available secure access methods, such as
20 pre-shared key and digital certificates, that are available in using the VPN. In addition, policy table **320** includes a preference order for establishing secure connections when multiple access methods are available. For example, a VPN may prefer using digital certificates
25 to establish secure connections. However, if the computer system is unable to make a secure connection using a digital certificate, a pre-shared key method may also be available as a second course of action.

 Pre-shared keys table **330** includes a list of common,
30 or shared, keys for each tunnel pair that uses a pre-shared key security method. Computers using a pre-shared key have the same key to derive encryption and

Docket No. AUS920010449US1

decryption keys. The pre-shared key is often provided to the computer system or the user in a way to reduce the chance that the key is misappropriated. For example, a pre-shared key may be mailed from a company to a client.

- 5 The client then uses the pre-shared key to establish secure communications with the company computer system. Different pre-shared keys are used for each combination of computer systems. In this manner, if one pre-shared key is compromised only data at the two systems using
10 that key are in jeopardy.

- Digital certificate table **340** includes a list of certificates (Public Keys) for each tunnel pair that uses digital certificates to secure communications. In addition, digital certificate table **340** may include
15 signing digital certificate keys used for Certificate Revocation List servers to determine whether a given certificate has been revoked. Public key encryption uses a private key to encrypt information destined for a given computer system. The receiving computer system deciphers
20 the information by using the sender's public key. The local computer system's private key is also included in digital certificate table **340**.

- Figure 4** shows a flowchart of the creation of a tunnel using VPN configuration data. Processing
25 commences at **400** whereupon a remote computer identifier is retrieved (input **405**) corresponding to a remote computer to be connected in a VPN with the current computer system. The remote computer ID is typically received from a user command or IKE message. The remote
30 computer ID is retrieved for both the initiator and the responder. The local-remote endpoints pair corresponding to the remote computer system identifier and the local

Docket No. AUS920010449US1

computer identifier is selected from the endpoints table (step **410**). The ID Rules List links the local-remote endpoints pair to a security policy name that is used in selecting the security policy (see step **440**). A

5 determination is made as to whether the endpoints pair was found (decision **415**). If the pair was not found, decision **415** branches to "no" branch **420** whereupon an error is reported that the user needs to configure a tunnel with the remote computer system before the tunnel
10 can be used (step **425**) and processing terminates (end **430**). Additionally, step **425** could invoke a configuration screen allowing the user to configure the tunnel with the remote computer by supplying the needed access information.

15 If the pair was found in the endpoints table, decision **415** branches to "yes" branch **435** whereupon a policy corresponding to the local-remote pair is selected from the policy table (step **440**). The policy includes a proposal list with separate initiator and responder
20 proposals. Proposals have general characteristics, like lifetimes and transform names. Transforms include specific encryption algorithms, hash algorithms, and authentication methods being proposed. A determination is made as to whether a corresponding policy was found
25 (decision **445**). If a corresponding policy was not found, decision **445** branches to "no" branch **450** whereupon a default policy is used (step **455**). For example, a default policy could be used to use a digital certificate (if available), before attempting to use any available
30 pre-shared keys. If the policy is found, decision **445** branches to "yes" branch **460**.

Docket No. AUS920010449US1

The initiator proposes one or more authentication methods to the responder in the order of initiator's preference (predefined process **465**, see **Figure 6** for further details). The initiator receives the responder's
5 selection of an authentication method (step **470**). A determination is made as to whether an error occurred in receiving the responder's selection (decision **475**). If an error occurred, decision **475** branches to "yes" branch **480** whereupon processing terminates at **485**. On the other
10 hand, if an error did not occur, decision **475** branches to "no" branch **488** whereupon a secure phase 1 tunnel is created between the initiator and the responder for setting up the phase 2 negotiations to select security choices for data traffic (predefined process **490**, see
15 **Figure 5** for further details). Predefined process **490** includes validating IDs, certificates, or pre-shared keys as well as checking the "liveliness" of the connection that the other computer matches the retrieved endpoint computer description during the entire conversation.
20 After predefined process **490**, create phase 1 tunnel processing terminates at **495**.

Figure 5 shows a flowchart of the details involved in creating a secure tunnel using the VPN configuration data. Processing commences at **500** whereupon the local
25 computer connects to the remote computer using the selected authentication method (step **505**). A determination is made as to whether the authentication method uses a digital certificate (decision **510**). If the authentication method uses a digital certificate,
30 decision **510** branches to "yes" branch **545** whereupon certificate processing commences.

Docket No. AUS920010449US1

On the other hand, if the access method does not use a digital certificate, decision **510** branches to "no" branch **515** whereupon a pre-shared key corresponding to the remote computer system is selected from the pre-shared key table (step **520**). A determination is made as to whether the pre-shared key is found (decision **525**). If the pre-shared key is not found, decision **525** branches to "no" branch **526** whereupon an error is returned at **590**.

If the pre-shared key is found, decision **525** branches to "yes" branch **528** whereupon the local machine attempts to connect to the remote machine using the selected pre-shared key (step **530**). A determination is made as to whether the local machine successfully connected to the remote machine (decision **535**). If the local machine did not successfully connect to the remote machine, decision **535** branches to "no" branch **536** whereupon an error is returned at **590**. On the other hand, if the local machine successfully connects to the remote machine, decision **535** branches to "yes" branch **538** whereupon processing returns to the calling routine (return **595**, see **Figure 4**).

Figure 6 is a flowchart showing steps performed in using policies to communicate through phase 1 and phase 2 processing.

In Phase 1, Initiator **600** commences by proposing (step **610**) specifications, authentication methods, and encryption algorithms to responder **605**. Responder, in turn, receives the proposal (step **615**) and selects an authentication method, specifications, and an encryption algorithm from the proposal and returns the selection to the initiator (step **620**). Responder expects to receive

Docket No. AUS920010449US1

these specifications in a DTD file which follows the standard format, as depicted in **Figure 7**. The initiator receives the responder's selection (step **625**). A Diffie-Hellman key exchange is performed between the
5 initiator and responder (steps **640** and **645**) and authentication data is exchanged depending upon the selected authentication method.

Each party, the initiator and the responder, establishes an Internet Security Association and Key
10 Management Protocol (ISAKMP) Security Association (steps **650** and **655**) to use in securing information sent between the computer systems. In Phase 2 processing, each system creates IPsec Security Associations for securing data traffic sent between the systems by negotiating one or
15 more Security Associations and the systems exchange IP addresses by using phased IDs and policies (steps **660** and **670**, for further details about IDs and policies see **Figure 7**). After the IDs have been exchanged and a security association has been negotiated, each system
20 sends and receives protected data traffic using the established policies and profiles (steps **670** and **675**).

Figure 7 depicts a high level flow chart which illustrates establishing a standard format to use by any operating system and any machine type to automatically
25 configure IP security tunnels in accordance with the present invention. The process starts as depicted by block **700** and thereafter passes to block **702** which illustrates establishing a standard format as a document type definition (DTD) file for specifying IP security
30 tunnels. A DTD file defines a collection of elements that may appear in an XML file. Next, block **704** depicts including a root element in the standard. The following

Docket No. AUS920010449US1

is an example of a root element:

```
<!ELEMENT AIX_VPN ((IKEProtection|IKEGroup|IKETunnel|
    IKEPre-sharedKey|IPSecProposal|
    IPSecProtection|IPSecTunnel)+)>
```

- 5 Any combination of IKEProtection, IKEGroup, IKEPre-sharedKey, IKETunnel, IPSecProposal, IPSecProtection, IPSecTunnel elements may be included in the root element. Any number of occurrences of each element may be included in the root element.
- 10 Block **706** illustrates including a protection element in the standard which includes a listing of IKE transforms. The following is an example of a protection element:

```
<!ELEMENT IKEProtection (IKETransform+)>
15 <!ATTLIST IKEProtection
    IKE_ProtectionName ID #REQUIRED
    IKE_Role (Initiator|Responder|Both|Neither)"Both"
    IKE_XCHGMode (Main|Aggressive)"Main"
    IKE_KeyOverlap CDATA "5"
    IKE_Flags_UseCRL(Yes|No)"No"
20 IKE_ResponderKeyRefreshMaxMinutes CDATA "480"
    IKE_ResponderKeyRefreshMinMinutes CDATA "15"
    IKE_ResponderKeyRefreshMinKB CDATA #IMPLIED
    IKE_ResponderKeyRefreshMaxKB CDATA #IMPLIED
25 >
```

- Thereafter, block **708** depicts including a transform element in the standard. A list of transform elements will be used for phase 1 security associations negotiations. The following is an example of a transform element:
- 30

```
<!ELEMENT IKETransform EMPTY>
<!ATTLIST IKETransform
```

Docket No. AUS920010449US1

```

        IKE_AuthenticationMethod (Preshared_key |
RSA_signatures)

                                "Preshared_key"
        IKE_Encryption (DES-CBC | 3DES-CBC) "3DES-CBC"
5      IKE_Hash (SHA | MD5) "SHA"
        IKE_DHGroup (1 | 2 ) "2"
        IKE_KeyRefreshMinutes CDATA "480"
>

```

The process then passes to block **710** which illustrates including a group element in the standard. This element can contain multiple identification elements. The purpose of this element is to allow the same protections and policies to be shared by multiple IDs. The following is an example of a group element:

```

15 <!ELEMENT IKEGroup (IKEID+)>
    <!ATTLIST IKEGroup
        IKE_GroupName ID #REQUIRED
    >

```

Next, block **712** depicts including an identification element in the standard. This element includes identification types that can be used by both phase 1 and phase 2 tunnels. However, not all of the identification types are valid in both phases. Phase 1 can use ASN1_DN, FQDN, User_FQDN, and KEYID. Phase 2 can use IPV4_Subnet, IPV6_Subnet, IPV4_Address_Range, and IPV6_Address_Range. Both phases can use IPV4_Address and IPV6_Address. The protocol and port attributes are only valid in phase 2. The following is an example of an identification element:

```

30 <!ELEMENT IKEID (ASN1_DN | FQDN | User_FQDN |
    IPV4_Address |
        IPV6_Address | KEYID | IPV4_Subnet |

```

Docket No. AUS920010449US1

```

IPV6_Subnet |
                IPV6_Address_Range |
IPV4_Address_Range)>
<!ATTLIST IKEID
5         Protocol CDATA "0"
          Port      CDATA "0"
>

```

Thereafter, block **714** illustrates including a tunnel element in the standard. This element defines the phase 1 security association endpoints and the IKEProtection element to be used for the negotiation. The following is an example of a tunnel element:

```

10 <!ELEMENT IKETunnel (IKELocalIdentity,
    IKERemoteIdentity)>
15 <!ATTLIST IKETunnel
    IKE_TunnelName ID #REQUIRED
    IKE_ProtectionRef IDREF #REQUIRED
    IKE_Flags_MakeRuleWithOptionalIP (Yes | No) "No"
    IKE_Flags_AutoStart (Yes | No) "No"
20 >

```

The "MakeRuleWithOptionalIP" field specifies whether another entry will be put in the rules list using the optional IP address specified in the remote identity element. If this field is set to "no", more than one tunnel can be defined using the same optional IP address; however, the computer system cannot act as a responder in a main mode negotiation with this tunnel. If an optional IP address is specified for the local identity element when the "MakeRuleWithOptionalIP" is set to "no", the optional IP address will be silently discarded as extraneous information for that negotiation type.

Docket No. AUS920010449US1

The process then passes to block **716** which depicts including a local identity element and a remote identity element in the standard. These elements define the local and remote IDs. The following are examples of a local identity element and a remote identity element:

```

5  <!ELEMENT IKELocalIdentity (ASN1_DN | FQDN | User_FQDN |
    IPV4_Address |
    IPV6_Address | KEYID)>
    <!ELEMENT IKERemoteIdentity (ASN1_DN | FQDN | User_FQDN |
10  IPV4_Address | IPV6_Address
    | KEYID |
    IKEGroupRef)>

```

Next, block **718** illustrates including an ID type element in the standard. These following are examples of possible ID type elements which may be included in the standard:

```

15  <!ELEMENT IPV4_Address EMPTY>
    <!ATTLIST IPV4_Address
        Value CDATA #REQUIRED
20  >
    <!ELEMENT IPV4_Subnet EMPTY>
    <!ATTLIST IPV4_Subnet
        IPAddr CDATA #REQUIRED
        Netmask CDATA #REQUIRED

The process then passes to block **720**, which depicts
 30 including a remote pre-shared key ID element in the
 standard. This element is the ID definition for remote
 pre-shared key. The following is an example of a remote

Docket No. AUS920010449US1

pre-shared key ID element:

```
<!ELEMENT IKEPresharedRemoteID (PK_ASN1_DN | PK_FQDN |
                                PK_User_FQDN |
                                PK_IPV4_Address |
5                                PK_IPV6_Address |
                                PK_KEYID)>
```

Block **722**, then, illustrates including a pre-shared key element in the standard. This element is the ID definition for the pre-shared key. The following is an example of a pre-shared key element:

```
<!ELEMENT PK_IPV4_Address EMPTY>
<!ATTLIST PK_IPV4_Address
          Value CDATA #REQUIRED
>
15 <!ELEMENT PK_IPV6_Address EMPTY>
   <!ATTLIST PK_IPV6_Address
          Value CDATA #REQUIRED

   <!ATTLIST PK_ASN1_DN
30          Value CDATA #REQUIRED
   >
   <!ELEMENT PK_KEYID EMPTY>
   <!ATTLIST PK_KEYID
```

Docket No. AUS920010449US1

Value CDATA #REQUIRED

>

Next, block **724** depicts including an IPsec proposal element in the standard. This element includes a list of

5 IPsec encapsulating security protocol (ESP) protocols and/or IPsec authentication header (AH) protocols elements. The following is an example of an IPsec proposal element:

10 <!ELEMENT IPsecProposal ((IPsecESPProtocol | IPsecAHProtocol)+)>

<!ATTLIST IPsecProposal

IPsec_ProposalName ID #REQUIRED

>

15 The process then passes to block **726** which illustrates including an IPsec ESP protocol element in the standard. This element defines an IPsec ESP protocol. The following is an example of an IPsec ESP protocol element:

<!ELEMENT IPsecESPProtocol EMPTY>

20 <!ATTLIST IPsecESPProtocol

ESP_Encryption (ESP_DES | ESP_3DES | ESP_NULL)
"ESP_DES"

ESP_Authentication (HMAC-MD5 | HMAC-SHA | NONE)
"HMAC-SHA"

25 ESP_EncapsulationMode (Tunnel | Transport)
"Tunnel"

ESP_KeyRefreshMinutes CDATA "60"

ESP_KeyRefreshKB CDATA #IMPLIED

>

30 Thereafter, block **728** depicts including an IPsec authentication header protocol element in the standard. This element defines an authentication header protocol.

Docket No. AUS920010449US1

The following is an example of an authentication header protocol element:

```

5      <!ELEMENT IPsecAHProtocol EMPTY>
      <!--ATTLIST IPsecAHProtocol
          AH_Authentication (AH_MD5 | AH_SHA ) "AH_SHA"
          AH_EncapsulationMode (Tunnel | Transport )
              "Tunnel"
          AH_KeyRefreshMinutes CDATA "60"
          AH_KeyRefreshKB      CDATA #IMPLIED
10  >

```

Next, block **730** illustrates including an IPsec protection element in the standard. This element defines IPsec protection. The following is an example of an IPsec protection element:

```

15  <!ELEMENT IPsecProtection EMPTY>
      <!--ATTLIST IPsecProtection
          IPsec_ProtectionName ID #REQUIRED
          IPsec_ProposalRefs IDREFS #REQUIRED
          IPsec_Role (Initiator|Responder|Both|Neither)
20  "Both"
          IPsec_KeyOverlap      CDATA "5"
          IPsec_Flags_UseCommitBit (Yes | No) "No"
          IPsec_Flags_UseLifeSize (Yes | No) "No"
          IPsec_InitiatorDHGroup (0 | 1 | 2 ) "0"
25  IPsec_ResponderDHGroup (NO_PFS | GROUP_1 |
              GROUP_2 |
                      GROUP_1_OR_2 |
                      NO_PFS_OR_GROUP_1_OR_2)
                      "NO_PFS_OR_GROUP_1_OR_2"
30  IPsec_ResponderKeyRefreshMaxMinutes CDATA "120"
          IPsec_ResponderKeyRefreshMinMinutes CDATA "1"
          IPsec_ResponderKeyRefreshMaxKB CDATA #IMPLIED

```

Docket No. AUS920010449US1

IPSec_ResponderKeyRefreshMinKB CDATA #IMPLIED

>

The process then terminates as depicted by block **732**.

Figure 8 illustrates a high level flow chart which depicts automatically configuring an IP security tunnel using a standard format in accordance with the present invention. The process starts as depicted by block **800** and thereafter passes to block **802** which depicts generating an XML file under the guidelines of the standard format defined by the DTD file described in more detail in **Figure 7**. Next, block **804** illustrates including elements from the standard as necessary to properly configure an IP security tunnel. Thereafter, block **806** depicts processing the XML file. Processing this file automatically configures an IP security tunnel. The process then terminates as depicted by block **808**.

Below is an example of an XML file that configures a tunnel under the guidelines of the standard.

```
<?xml version="1.0" ?>
20 <!DOCTYPE AIX_VPN SYSTEM "ike.dtd">

10

</AIX_VPN>

15 In this example, explicit policy and tunnel choices are being specified, namely using RSA signature mode for authentication with Diffie Helmann group 1 with local identity 9.3.97.138 and remote identity 9.3.97.66. In this example, the use of DES with HMAC-MD5 and a refresh time of 28800 seconds are requested.

20 It is important to note that while the present invention has been described in the context of a fully functioning data processing system, those of ordinary skill in the art will appreciate that the processes of the present invention are capable of being distributed in the form of a computer readable medium of instructions and a variety of forms and that the present invention
25 applies equally regardless of the particular type of signal bearing media actually used to carry out the distribution. Examples of computer readable media include recordable-type media, such as a floppy disk, a hard disk drive, a RAM, CD-ROMs, DVD-ROMs, and
30 transmission-type media, such as digital and analog communications links, wired or wireless communications links using transmission forms, such as, for example,

Docket No. AUS920010449US1

radio frequency and light wave transmissions. The computer readable media may take the form of coded formats that are decoded for actual use in a particular data processing system.

- 5 The description of the present invention has been presented for purposes of illustration and description, and is not intended to be exhaustive or limited to the invention in the form disclosed. Many modifications and variations will be apparent to those of ordinary skill in
- 10 the art. The embodiment was chosen and described in order to best explain the principles of the invention, the practical application, and to enable others of ordinary skill in the art to understand the invention for various embodiments with various modifications as are
- 15 suited to the particular use contemplated.
